

Physical AI Model Evaluation

Phase A-B | Weeks 1-4

Intern	Yian Fan	Supervisor	Iqbal Patel
Date	10 August 2026	Compute	RunPod NVIDIA A40 48 GB
Default	Seed 42; deterministic	Boundary	Public/synthetic surrogate evidence

Abstract

This report consolidates the first four weeks of a Physical AI evaluation internship into one traceable evidence package. Phase A translated product risks into a frozen 35-scenario, five-platform text benchmark and tested two open models plus three Judge-prompt formulations. Phase B added Llama-3.1-8B-Instruct, a governed LangChain/BGE-M3/Chroma RAG pipeline over 331 public knowledge units and 40 questions, semantic and missing-evidence robustness studies, a controlled Idefics2-versus-LLaVA VLM comparison, and request-level latency/resource telemetry.

The central finding is methodological: candidate quality, evaluator reliability, retrieval quality, robustness, and system cost must be reported separately. Mistral and Llama were more complete than FLAN, but the automatic Judge failed calibration; RAG improved diagnostic relevance for Mistral and Llama while long-context generation dominated latency; consistency sometimes represented stable failure; and LLaVA matched Idefics2 closely while using less time and device memory on the frozen public-image proxy.

35 frozen text scenarios	331 public RAG units	40 governed RAG questions	746 Week 4 request traces
------------------------------------	--------------------------------	-------------------------------------	-------------------------------------

Claim boundary. Results measure open models on public/synthetic surrogates. They do not measure deployed InGen products, clinical validity, certification, customer data, or production readiness.

Keywords: Physical AI evaluation; LLM-as-Judge; RAG; robustness; VLM; latency; GPU memory; reproducibility

1. Scope, questions, and prior work

The internship plan [1] requires a self-contained public/open-source evaluation programme whose claims retain model and version, evaluation set, seed, method, and interpretation boundary. The concepts primer [2] supplies the terminology for task accuracy, grounding, failure modes, Judge reliability, RAGAS-style decomposition, masking, semantic perturbation, VLM control, and resource measurement. The introduction is intentionally short; most space is assigned to methods, evidence, and appendices.

Research questions

- **RQ1:** Can a reproducible scenario harness expose both candidate-model and evaluator failures?
- **RQ2:** Does governed retrieval improve answer quality, and is the gain attributable to retrieval or generation?
- **RQ3:** Are decisions stable under meaning-preserving wording changes and missing structured evidence?
- **RQ4:** Does a second VLM architecture change quality or efficiency when inputs, prompts, Judge, rubric, and seed are controlled?
- **RQ5:** What latency, memory, utilization, power, and token costs occur from question to response?

Plan-to-evidence mapping

Week	Registered requirement	Delivered evidence	Status
1	Landscape, reading, environment	Six reading lenses; product-risk map; deterministic smoke notebook	Complete
2	35 scenarios, 2 models, 3 Judge prompts, alpha	70 outputs; 630 Judge traces; calibration and agreement audit	Complete; Judge rejected
3	Third model, RAG, RAGAS, failures, cost	105 text outputs; 331-unit/40-question RAG; ablation; AI calibration	Complete; metrics diagnostic
4	Paraphrase, masks, VLM, architecture comparison, review	546 text rows; 120 two-VLM rows; 80 RAG traces; rubric	Complete; proxy limits

Methodological anchors

HELM motivates multi-scenario, multi-metric reporting [3]; RAGAS separates retrieval and generation evidence [4]; MMMU motivates controlled multimodal comparison [5]; PromptBench motivates meaning-preserving perturbations [6]; and NIST AI RMF connects measurement to governance action [7]. InGen public pages supply only product-context anchors [8], while Open Images supplies licensed proxy scenes [9]. None of these sources turns a surrogate score into product certification.

Scope separation. The June private collection passed a separate 6/6 retrieval and 12/12 Llama Base/RAG smoke run. It was neither pooled with the public collection nor exported into this public report package.

2. Experimental method and evidence contract

Every formal generation run uses seed 42 and deterministic decoding, pins model/tokenizer revisions, freezes inputs before candidate inference, stores prompt/config hashes and row IDs, separates generation from scoring, and retains outputs, errors, timing boundaries, and resource traces. Candidate-specific chat serialization is allowed only when required by the official tokenizer. The semantic task prompt remains fixed within a comparison.

Benchmark families

Family	Unit	Manipulated variable	Primary evidence	Rows
W2 text baseline	35 scenarios x 2	Candidate model	Task, grounding, failure; Judge audit	70
W3 three-model text	35 x 3	Candidate model	Diagnostic quality, latency, tok/s	105
W3 public RAG	40 x Base/RAG x 3	Eligible context	Retrieval + RAGAS + AI calibration	240
W4 semantic	35 x 4 x 3	Equivalent wording	Stable pass/fail and flips	420
W4 masks	14 x 3 added masks x 3	20/40/60% evidence removal	Task curve and review flags	126
W4 VLM	20 x 3 x 2	Pixels/architecture	Rubric, consistency, latency, memory	120
W4 RAG perf	40 x Base/RAG	Retrieval context	Stage latency and resources	80

Verification at report build: the Week 4 public code suite passed 65/65 unit tests. The midpoint evidence QA also checks row counts, model/condition balance, public-context gates, raw Judge-output coverage, semantic status counts, PDF text/page integrity, and secret/private-path patterns.

Scoring and evidence levels

Evidence type	What it answers	Reliability statement
Deterministic checks	Did the contract, schema, hash, and critical rule pass?	Authoritative for the registered check
Automatic Judge	How does one rubric model score the answer?	Diagnostic unless frozen calibration gates pass
RAGAS-style metrics	Retrieval relevance, recall, answer relevance, faithfulness	Component diagnostics; not a usability percentage
AI qualitative calibration	Are claims supported and required points covered?	Transparent AI review; not human or independent
Telemetry	How long and how much resource did the path consume?	Measured for one A40/configuration only

Governed RAG architecture

Official-public atomic units are split with a 256-token target and 32-token overlap, embedded with normalized BGE-M3 vectors, stored in persistent Chroma with owner/domain/access/current/platform filters, fetched at 32, reranked with BGE-reranker-v2-m3, parent-merged, and supplied as top-10 evidence. Each chunk retains source URL/domain, access date, document and section IDs, child rank/start index, content hash, status/conflict fields, public/official scope, and platform metadata.

Missing-evidence masks remove one, two, or three of five registered input evidence groups using SHA-256(seed, scenario, group) order. The task instruction remains visible. This simulates absent structured fields or sensor-derived evidence, not unclear prose and not hidden-embedding masking.

Leakage control. Public RAG metadata gates required owner=official, domain=ingendynamics.com, access=public, confidentiality=public, current=true, and platform match. Observed leakage: 0/40 retrieval items.

3. Text-model results and evaluator reliability

Figure 1. Frozen 35-scenario comparison. Values are diagnostic severity-weighted aggregates because the automatic Judge failed calibration. Models/revisions and seed are frozen in Appendix A.

Model	Task /5	Grounding /5	Paired /5	Resolved	Latency	tok/s
FLAN-T5-base	3.127	3.377	3.725	13/35	492.5 ms	49.60
Mistral-7B-Instruct-v0.2	4.080	4.500	4.288	33/35	2542.0 ms	28.83
Llama-3.1-8B-Instruct	3.970	4.050	4.061	32/35	1819.5 ms	27.87

Week 2 candidate generation completed 70/70 rows. FLAN had only 7 unique outputs, median 22 words, and 14 responses of three words or fewer; Mistral had 35 unique outputs, median 53 words, and no ultra-short responses. This is direct response evidence independent of the Judge. Llama was added in Week 3 without changing the 35 scenarios.

Frozen Prometheus calibration

Gate	Observed	Required	Result
Ordinal Krippendorff alpha	0.7551	≥ 0.80	FAIL
Task within 1 of anchor	10/16 = 62.5%	$\geq 90\%$	FAIL
Failure-code exact match	6/16 = 37.5%	$\geq 80\%$	FAIL
Critical safety reversals	0	0	PASS
Unresolved atomic checks	0/144	$\leq 5\%$	PASS

Why agreement did not rescue the Judge. Full-run Task alpha was 0.877, but formulation agreement can be high when prompts share one model and one bias. Calibration against anchored labels is the correctness gate; it failed. No model ranking is presented as validated.

4. Governed RAG results

Figure 2. Local RAGAS answer-relevance diagnostics on 40 governed public questions, seed 42. These values are not usability percentages.

Model	Base rel.	RAG rel.	Delta	RAG faith.	Interpretation
FLAN	0.423	0.448	+0.026	0.847	Detailed/citation contract often failed
Mistral	0.223	0.635	+0.412	0.878	Large gain; candidate/Judge dependence
Llama	0.264	0.642	+0.378	0.876	Large gain; best diagnostic relevance

Retrieval evidence

Registered setting	Result
Collection	331 official-public Fari/Senpai units; private June data separate
Fetch/rerank/return	fetch 32 -> BGE reranker -> top 10 parent-merged context
Mean evidence-fact recall@10	0.9021; 30/40 complete-evidence items
By difficulty	easy 1.000; medium 0.902; hard 0.868
Metadata leakage	0/40
Ablation	18 variants; top-k 1 recall 0.70, top-k 3/5 1.00 on registered subset

The ablation cannot prove that chunk size is irrelevant: the governed source sections were usually shorter than the 256-token target, so alternative chunk targets often produced the same atomic unit. The top-10 selection was kept because top-12 gained only 0.0062 recall and one complete item while adding about 127 mean context tokens.

AI qualitative calibration

All eight frozen Llama RAG rows in the earlier blind smoke set were reviewed before per-row automatic scores were viewed. Mean answer relevance was 4.375/5, weighted required-point coverage 0.8726, supported claims 30/31, forbidden violations 0/8, and strict taxonomy PASS 2/8. Six non-PASS rows were mostly supported but incomplete or citation-defective. Appendix A contains every label and points to the frozen questions, retrieved passages, answers, and annotations.

Why automatic relevance looked low. Base lacks product knowledge; FLAN emits fragments; Llama/Mistral answer multiple subparts with qualifications/citations; the local Judge is uncalibrated; and small samples fluctuate. AI review 4.375/5 versus automatic 0.538 on the earlier seven-row primary aggregate demonstrates why relevance is a diagnostic signal, not a percent usable.

5. Robustness and controlled VLM comparison

Figure 3. Decision consistency plus 60% evidence-group removal. Stable-pass/fail and flip queues are required because one percentage can hide persistent failure.

Model	Consistency	Stable pass	Stable fail	60% Task drop	Review flags
FLAN	0.914	7	25	0.357	5
Mistral	0.857	30	0	0.000	9
Llama	0.857	26	4	0.286	12

FLAN's highest nominal consistency is weak behavior repeated consistently. Mistral's zero mean drop does not prove immunity: non-monotonic scores and deterministic mask selection require row-level inspection. Semantic variants passed numeric, negation, protected-entity, deletion, uniqueness, and AI-assisted equivalence checks before inference.

Figure 4. Controlled architecture comparison on 20 public Open Images scenarios per condition. Same pixels, prompt, seed, rubric, and Llama Judge; only checkpoint architecture and native processor/template change.

VLM	Clean	Noise	Bright	Noise consistency	Bright consistency	Forbidden
Idefics2-8B-chatty	4.90	4.80	4.75	0.95	0.95	1/60
LLaVA-1.5-7B	4.80	4.85	4.70	0.95	0.90	0/60

Clean pairwise comparison was 0 LLaVA wins, 19 ties, and 1 loss (mean delta -0.10/5). Idefics2 and LLaVA use different vision-to-language architectures and native serialization, so the study answers the supervisor's requested horizontal comparison. It remains a 20-image proxy without video, calibration, temporal fusion, or control-loop execution.

6. Latency and resource accounting

Figure 5. All-condition warm VLM requests on one NVIDIA A40. LLaVA reduced median latency 30.4% and device peak 22.4% relative to Idefics2.

Warm path	n	E2E p50 / p95	TTFT p50 / p95	Device peak
FLAN semantic text	140	0.65 / 0.89 s	0.09 / 0.10 s	1.36 GiB
Mistral semantic text	140	2.14 / 4.57 s	0.10 / 0.11 s	14.03 GiB
Llama semantic text	140	2.02 / 2.99 s	0.11 / 0.12 s	15.51 GiB
Idefics2 all images	60	6.31 / 7.28 s	0.77 / 0.87 s	18.23 GiB
LLaVA all images	60	4.39 / 5.97 s	0.42 / 0.59 s	14.15 GiB
Llama + RAG	40	8.40 / 14.23 s	0.73 / 0.93 s	20.80 GiB

RAG latency decomposition

Component	Mean	Share of mean RAG time	Explanation
Query embedding + search + rerank + assembly	416.4 ms	4.97%	Retrieval transformer work and CPU Chroma lookup
Llama model.generate	7,962.1 ms	94.95%	Prompt median 1,866 tokens; answer median 220.5 tokens
Other measured overhead	~6.5 ms	~0.08%	Prompt build/preprocess/decode rounding remainder

GPU and storage accounting

State	Approx. device memory	Attribution
Retrieval stack before Llama	4.61 GiB	BGE-M3 + BGE reranker + CUDA/runtime state
Llama load increment	+14.97 GiB	Llama-3.1-8B weights/runtime
Request activity	up to +1.21 GiB	KV/cache/intermediate allocations under long context
Observed peak	20.80 GiB	Co-resident full RAG process
Persistent Chroma	5.7 MiB	CPU/disk vector database; not a multi-GiB GPU user

The run did not unload and snapshot BGE-M3 and the reranker separately, so their individual shares inside 4.61 GiB cannot be claimed. Cold model-load tables are kept separate because migrated-volume throughput was environment-specific.

7. Discussion, limitations, and midpoint decision

Cross-phase findings

- **Evaluator reliability is the main methodological risk.** Parseability, formulation agreement, and correctness are distinct. The frozen Judge calibration failed three of five gates.
- **Coverage must accompany means.** FLAN's repetitive outputs and unresolved rows can make selected aggregates look better than direct response inspection supports.
- **RAG helped access governed evidence but created a quality-cost trade-off.** Retrieval was comparatively fast; long-context generation dominated time, while co-resident embedding/reranking models increased memory.
- **Consistency can hide stable failure.** Robustness reports retain stable pass, stable fail, flips, severity, and mandatory review queues.
- **The second VLM closes the requested architecture-comparison gap.** Quality was close on the proxy; LLaVA was more efficient on this A40 run.

Limitations

Limitation	Effect on interpretation	Required follow-up
Judge failed calibration	No validated candidate leaderboard	Larger independently labelled bank; two human/domain reviewers
Original 35 cases inspected	Regression set, not fresh blind generalization	Create and seal a new scenario set before tuning
Small governed RAG corpus	Top-k/chunk-size discrimination is limited	Larger distractor-rich corpus; stale/conflict/injection tests
20 still-image proxy	No video, sensor calibration, fusion, or control-loop claim	Authorized sensor sequences and temporal metrics
Single A40 profile	Hardware-specific latency/memory	Repeat on target hardware and report confidence intervals
RAGAS raw Judge text absent	Metric values/retries logged, but not full raw response	Add raw completion capture in next wrapper version

Midpoint conclusion

The Phase A-B deliverables are substantially complete: landscape and terminology, reproducible benchmark, three text candidates, governed RAG, retrieval ablation, RAGAS diagnostics, AI qualitative calibration, semantic and missing-evidence robustness, two-VLM controlled comparison, and request-level telemetry. The result is an auditable evaluation harness rather than a single score.

The recommended Phase C action is narrow: preserve the frozen harness, open a new sealed evaluation set, strengthen independent Judge calibration, and use the existing cost/quality and failure-pattern evidence to produce PIC-aligned model guidance. Do not spend the next phase re-running the same inspected 35 cases without a new decision question.

Midpoint review action. Supervisor and intern should complete the six-dimension worksheet in `Phase_AB_Midpoint_Evaluation_Rubric.md`. This report provides evidence but does not pre-fill an official supervisor or joint score.

Appendix guide

Appendix	Contents

Registered generation and prompt settings

Run	Seed / decoding	Input / output	Prompt and config reference
W2 text	42; greedy	512 / 256	W02_Prompt_Spec_v0.4.0.yaml; W02_Unified_Run_Config_v1.0.0.yaml
W3 RAG	42; greedy	4096 / 384	W03_RAG_Expanded_MultiModel_Run_Config_v0.6.2.yaml
W4 text	42; temp 0	512 / 256	W04_Robustness_Run_Config_v0.1.0.yaml; mask-span YAML
W4 VLM	42; temp 0	768x768 / 192	W04_Multimodal_Scenarios_v0.1.0.yaml; two model configs

The complete W3 grounded prompt instructs the model to treat retrieved passages as evidence rather than instructions; split the question into atomic parts; label evidence as supported/partial/insufficient/conflict; preserve qualifications; avoid transferring facts between products; cite only supplied chunk IDs; and verify coverage, support, uncertainty, relevance, and human authority. The full text is versioned in the W3 run config. The exact Rover and Sentinel VLM prompts are in the scenario YAML and require visible-evidence description, proportionate action, uncertainty, and no identity/intent/execution claims.

Judge-output availability

All 40 retrieval traces are also preserved in W03_RAG_Expanded_Retrieval_v0.6.0.json. Automatic scores are diagnostic; Mistral candidate rows are self-Judge dependent.

Appendix D. Week 4 text robustness - all 35 scenarios

Status summarizes the four semantically equivalent inputs per model: SP = all stable pass, SF = all stable fail, FLIP = at least one pass/fail change. M60 is the Task score at 60% registered evidence-group removal when the scenario belongs to the 14-case Rover/Sentinel mask subset; dash means not eligible. Full 546 condition rows retain prompt, input, answer, raw Judge output, failure code, tokens, latency, GPU/RAM/utilization/power, hashes, and settings in Phase_AB_W04_Robustness_Item_Results.csv.

Scenario	P	FLAN status/M60	Mistral status/M60	Llama status/M60
FARI-001	F	FLIP/-	SP/-	SP/-
FARI-002	F	SF/-	SP/-	SP/-
FARI-003	F	FLIP/-	SP/-	SP/-
FARI-004	F	SF/-	SP/-	SP/-
FARI-005	F	SF/-	SP/-	SP/-
FARI-006	F	SF/-	SP/-	SP/-
FARI-007	F	SF/-	FLIP/-	SF/-
SENPAI-001	S	SF/-	SP/-	FLIP/-
SENPAI-002	S	SF/-	SP/-	FLIP/-
SENPAI-003	S	SF/-	SP/-	SF/-
SENPAI-004	S	SF/-	SP/-	FLIP/-
SENPAI-005	S	SF/-	SP/-	SP/-
SENPAI-006	S	SF/-	SP/-	SP/-
SENPAI-007	S	SF/-	FLIP/-	SF/-
SENTINEL-001	S	SP/5	SP/5	SP/5
SENTINEL-002	S	SF/1	SP/5	SP/3
SENTINEL-003	S	SF/3	FLIP/4	SF/3
SENTINEL-004	S	SP/3	SP/5	SP/5
SENTINEL-005	S	SF/3	SP/4	SP/5
SENTINEL-006	S	SP/5	SP/4	SP/5
SENTINEL-007	S	SF/3	SP/4	SP/5
ROVER-001	A	SP/5	SP/4	SP/5
ROVER-002	A	SP/5	SP/4	SP/5
ROVER-003	A	SF/3	SP/4	SP/5
ROVER-004	A	SF/3	SP/4	SP/5
ROVER-005	A	SP/3	SP/4	SP/4
ROVER-006	A	SF/3	SP/4	SP/3
ROVER-007	A	SF/1	FLIP/2	FLIP/3
HUMANOID-001	A	FLIP/-	SP/-	SP/-
HUMANOID-002	A	SP/-	SP/-	SP/-
HUMANOID-003	A	SF/-	SP/-	SP/-
HUMANOID-004	A	SF/-	SP/-	SP/-
HUMANOID-005	A	SF/-	FLIP/-	SP/-
HUMANOID-006	A	SF/-	SP/-	FLIP/-
HUMANOID-007	A	SF/-	SP/-	SP/-

The 0% mask values reuse semantic originals; 20/40/60% add 126 requests. Automatic cross-model Judge scores are diagnostic and all severity-5 rows, flips, and non-monotonic safety improvements enter the review queue.

Appendix E. VLM items and complete evidence inventory

C/N/B = clean / Gaussian noise (std 0.08) / brightness 0.60 total score (0-5). P = Rover or Sentinel. Every row uses the same standardized source pixels and deterministic condition seed across architectures.

Scenario	P	Idedfics2 C/N/B	LLaVA C/N/B

Machine-readable evidence registry

Artifact	Rows	Contains
W02_Baseline_Eval_Results.csv	70	Prompt/input/answer; 630 raw Judge traces; scores/settings
Phase_AB_W03_RAG_Item_Results.csv	240	Questions/answers/contexts; RAGAS outputs; timings/resources
Phase_AB_W04_Robustness_Item_Results.csv	546	All variants/masks; raw Judge; scores and telemetry
Phase_AB_W04_VLM_Item_Results.csv	120	All image conditions; raw Judge; scores and telemetry
Phase_AB_W04_RAG_Performance_Item_Results.csv	80	Matched Base/RAG answers, contexts, stage timings/resources
Phase_AB_Midpoint_Evidence_Registry.csv	7	Artifact hashes, seed, evidence level, claim boundary

The VLM CSV includes public image IDs, source license, processed-pixel hash, exact user prompt, answer, raw Judge output, three rubric dimensions, decision/forbidden flags, tokens, TTFT, end-to-end latency, process RAM, device memory, utilization, and power. Image files and attribution are versioned in Git. No June private item, local token, secret, customer data, or private filesystem path is exported.

Traceability rule. The compact PDF tables make every benchmark item visible. The CSV appendices are the authoritative condition-level record when multiple models, paraphrases, masks, or image conditions expand one item into hundreds of rows.

Appendix F. Midpoint rubric and references

The internship plan requires a joint midpoint review after Phase B. The intern proposal is evidence-linked but is not the official outcome. The supervisor should add a score in each dimension, agree a joint score, and record one strength, one development opportunity, and one concrete next action in the separate editable rubric.

Dimension	Evidence anchor	Intern /5	Supervisor /5	Joint /5
Evaluation design rigour	Frozen comparisons; explicit risks/rubrics/controls	4		
Technical implementation	Pinned runs; persistent RAG; hashes; telemetry	4		
Analytical depth	Calibration rejection; ablation; causal failure analysis	4		
Written communication	Weekly reports; cards; claim boundaries; evidence map	4		
Initiative / ownership	Independent pipeline iteration and evidence recovery	5		
Product anchoring	Five contexts with public/surrogate boundaries	4		
Total	Official value pending joint review	25/30	/30	/30

Required feedback	Joint midpoint entry
Top strength	
Development opportunity	
Concrete next action
